

Nitty-gritty of Data and Exploratory Analysis with Python 3

Dev Skill Class 7

Jayanta Sarker Shuva

Data Analytics:

There are many tools available for data analytics in Python. In this course we will mainly focused on Numpy and Pandas.

Numpy:

The core data structure in NumPy is the ndarray object, which stands for N-dimensional array. An array is a collection of values, similar to a list. N-dimensional refers to the number of indices needed to select individual values from the object.

1-dimensional array

a	
a[0]	0
a[1]	3
a[2]	105
a[3]	30
a[4]	1

2-dimensional array

		b				
		b[0,0]	b[0,1]	b[0,2]	b[0,3]	b[0,4]
b[0,0]		0	3	105	30	1
b[1,0]		0	3	105	30	1
b[2,0]		0	3	105	30	1

Each value in a NumPy array has to have the same data type. NumPy data types are similar to Python data types, but have slight differences. You can find a full list of NumPy data types [here](#). Here are some of the common ones:

- bool: Boolean.
 - ✓ Can be True or False.
- int: Integer values.

- ✓ Can be int16, int32, or int64. The suffix 16, 32, or 64 indicates the number of bits.
- float: Floating point values.
 - ✓ Can be float16, float32, or float64. The suffix 16, 32, or 64 indicates how many numbers after the decimal point the number can have.
- string: String values.
 - ✓ Can be string or unicode, which are two different ways a computer can store text.

NumPy will automatically figure out an appropriate data type when reading in data or converting lists to arrays. You can check the data type of a NumPy array using the dtype property.

Matrix:

In mathematics, a matrix (plural: matrices) is a rectangular array of numbers, symbols, or expressions, arranged in rows and columns. For example, the dimension of the matrix below is 2×3 (read "two by three"), because there are two rows and three columns:

$$\begin{bmatrix} 6 & 4 & 24 \\ 1 & -9 & 8 \end{bmatrix}$$

A Matrix

(This one has 2 Rows and 3 Columns)

Matrix Multiplication:

Multiply a matrix by a single number or **Scalar Multiplication**:

$$2 \times \begin{bmatrix} 4 & 0 \\ 1 & -9 \end{bmatrix} = \begin{bmatrix} 8 & 0 \\ 2 & -18 \end{bmatrix}$$

(Note: A yellow arrow points from the scalar 2 to the top-left element 4, with the label 2x4=8 above it.)

These are the calculations:

$2 \times 4 = 8$	$2 \times 0 = 0$
$2 \times 1 = 2$	$2 \times -9 = -18$

Multiplying a Matrix by another Matrix or **Dot Product**:

"Dot Product"

$$\begin{bmatrix} 1 & 2 & 3 \\ 4 & 5 & 6 \end{bmatrix} \times \begin{bmatrix} 7 & 8 \\ 9 & 10 \\ 11 & 12 \end{bmatrix} = \begin{bmatrix} 58 \\ \end{bmatrix}$$

The "Dot Product" is where we **multiply matching members**, then sum up:

$$(1, 2, 3) \cdot (7, 9, 11) = 1 \times 7 + 2 \times 9 + 3 \times 11 \\ = 58$$

We match the 1st members (1 and 7), multiply them, likewise for the 2nd members (2 and 9) and the 3rd members (3 and 11), and finally sum them up.

$$\begin{bmatrix} 1 & 2 & 3 \\ 4 & 5 & 6 \end{bmatrix} \times \begin{bmatrix} 7 & 8 \\ 9 & 10 \\ 11 & 12 \end{bmatrix} = \begin{bmatrix} 58 & 64 \\ \end{bmatrix}$$

$$\begin{bmatrix} 1 & 2 & 3 \\ 4 & 5 & 6 \end{bmatrix} \times \begin{bmatrix} 7 & 8 \\ 9 & 10 \\ 11 & 12 \end{bmatrix} = \begin{bmatrix} 58 & 64 \\ 139 & 154 \end{bmatrix} \checkmark$$

Exercise:

Apple costs \$3 each
Cherry costs \$4 each
Blueberry costs \$2 each.

4 days item sales count as bellow –

	Mon	Tue	Wed	Thu
<i>Apple</i>	13	9	7	15
<i>Cherry</i>	8	7	4	6
<i>Blueberry</i>	6	4	0	3

Use Matrix multiplication and find out Day wise total sales amount.
